

System and method to transfer fluid

Technical field of the invention

5 The invention relates to a system to transfer fluid such as cryogenic fluids for instance natural gas in liquefied or condensate form from one structure to another, hereafter referred to as a platform and a vessel respectively and vice versa, where the system includes an offloading arm connecting the platform and the vessel and carrying at least one pipeline.

10 Background of the invention

It is known that some systems for the same purpose have been designed. The known systems include a Statoil system based on multi flexible pipes, a FMC system based on series of chiksan swivel joints, Bluewater underwater offloading system, Kvaerner Moss offloading arm based on double-arm construction, and Conoco
15 HiLoad system based on pipe bridge and others.

In particular, it is known from OTC Paper 14096 (presented at Houston, Texas in May 2002) that rigid articulated loading arms may be connected between an FPSO and a shuttle tanker. The rigid loading arms are hingedly connected together, and contain thermal insulation for hingedly connected pipelines within those loading
20 arms. The arrangement has to allow for continual rotational motion of significant amplitude between the hinged joints connecting the rigid articulated loading arms.

Other examples on transferral of fluids at sea are described in US 4671704 and GB 2029794.

The aim of the present invention is to provide a system for transfer of fluid between
25 two structures offshore, which is flexible, reliable in harsh weather conditions and economically feasible.

The aim of the invention is obtained by a system and method according to the following claims.

Disclosure of the invention

30 The invention relates to a system to transfer fluid via at least one pipeline from one structure to another structure. The structures may be floating or fixed relative to the ground, such as platforms, floating platforms, vessels, barges etc. The combination may be a combination of any of these. One of the structures has an offloading arm which is movable in two planes perpendicular to each other, so that it is movable in
35 three directions. A part of the offloading arm remote from the one structure is engagable with the other structure, so to allow linear and rotational movements between the structures. The pipeline for the transfer of fluid runs along the

offloading arm and is configured to compensate for movements between the two structures in the longitudinal direction of the offloading arm. The fluid may for instance be cryogenic fluid, such as liquefied or condensate natural gas.

5 At least one part of the pipeline along the offloading arm is attached to the offloading arm by means of at least one support moveable lengthwise relative to the offloading arm. This part of the pipeline includes at least one pipeline section, a first pipeline section, configured to compensate for movements in the longitudinal direction of the offloading arm. Other parts may be straight rigid pipe parts. The length of the first section, is determined by the type of compensation necessary for
10 the different uses, in relation to economics and type of configuration used.

One embodiment comprises the first pipeline section configured with V-shaped rigid pipelines with swivel joints. These pipe lines are especially adapted for fluids at low temperatures. The V-shaped rigid pipelines with swivel joints may be inverted and running in a generally vertical plane, generally parallel to the
15 offloading arm. Other configurations are also possible, like for instance V-shaped in a generally horizontal plane, or double V-shaped etc.

In another embodiment the first pipeline section may be configured as a spiral with the axis of the spiral extending mainly parallel with the longitudinal direction of the offloading arm, and where the spiral pipeline is capable of sustaining a spiral shape under the combined weight of the pipeline and fluid within the pipeline. A
20 combination of these embodiments would also be possible.

Normally the part of the pipeline which is connected to the offloading arm to allow movements lengthwise of the offloading arm, will also include at least a second rigid pipeline section. This second rigid pipeline section is connected to supports
25 moveable lengthwise relative to the offloading arm. Rigid pipeline sections may be on both sides of the first pipeline section.

The supports with which the part of the pipeline is movable along the offloading arm may be of many kinds. One is a wheel mounted trolley, others are blocks running on rails or blocks with brush-connection or running grooves.

30 The part of the pipeline remote from the one structure and engagable with the other structure is itself connected to or part of another support moveable lengthwise relative to the offloading arm. The connection between the offloading arm and the other of the structures may be formed as a pin downwardly dependant from the offloading arm, and rotatable about a vertical axis in a receptacle on the other of the
35 structure. Tension may be applied between the other structure and the part of the offloading arm engagable with that other structure, so to resist separation of the loading arm and the other structure.

5 The pipeline is connected to the respective structures by joints capable of accommodating angular and rotational movement between the pipeline and the respective structure. In one embodiment the pipeline is connected to one of the respective structures by a hinge joint and to the other of the respective structures by a universal joint. Normally the pipeline also has at least one joint arranged to compensate for thermal expansion and contraction relative to the offloading arm and/or either or both of the structures, whereby to allow optimum alignment of adjacent lengths of pipeline.

10 On the offloading arm there may be a plurality of pipelines extending between the structures.

15 The invention also includes a method of transferring fluid from one structure to another structure, in which one of the structures has an offloading arm which is movable in a vertical plane about a horizontal axis and which is also rotatable about a vertical axis, and which comprises the steps of arranging a part of the offloading arm to engage with the other structure, so to allow linear and rotational movement between the structures

20 The invented system is preferably a stern to bow (tandem) type offloading system. Based on the specific characteristics of the first pipeline section that in this case compensate relative distance and relative heeling of the platform and the vessel avoiding transfer of any loads or/ and bending moments to the connecting pipelines. The main components of the system ensure safe and efficient offloading of cryogenic fluid even in harsh offshore environment. The offloading arm is preferably installed on the platform's aft deck and the receiving terminal is installed on the vessel's forecastle deck, but one can consider other possibilities as for
25 instance the opposite or sideways even if this is not preferred.

Brief description of the drawings

Brief system description is presented on the following pages, with reference to the drawings where:

30 Fig. 1 shows one embodiment of the system according to the invention used in one instance between two vessels,

Fig. 2 shows side view of the crane, crane pedestal and crane column installed on the platform's deck,

Fig. 3 shows side view of one embodiment of the bridge type offloading boom, receiving terminal and pipe connectors installed on the vessel's forecastle deck,

35 Fig. 4 shows one embodiment of the connection between connector trolley and receiving terminal installed on the vessel's forecastle deck,

Fig. 5 shows a second embodiment of the system according to the invention used in one instance between two vessels,

Fig. 6 shows side view of a second embodiment of the bridge type offloading boom, receiving terminal and pipe connectors installed on the vessel's forecastle deck,

- 5 Fig. 7 shows a second embodiment of the connection between connector trolley and receiving terminal installed on the vessel's forecastle deck.

Description of the specific embodiments

The invention relates to a system to transfer fluid such as cryogenic fluids for instance natural gas in liquefied or condensate form from one to another structure,
10 as shown conceptual in fig. 1 and 5.

As shown in fig. 2, the invention comprises in both embodiments a crane pedestal 1 which is fastened to the aft deck of the platform. Crane column 2 is attached to the crane pedestal by slewing mechanism 3 comprising for example the roller bearings that provides rotating of crane column relative to the crane pedestal in vertical axis
15 relative to the platform. Rotation is provided by means of at least one motor preferably hydraulic one (not shown). Hinge joints 4 ensure rotating of the crane boom 5, represented by a torsional flexible bridge that permits relative heeling between the platform and the vessel and carrying one or more cryogenic pipelines, relative to the crane column. Winch 6 or hydraulic cylinder (not shown) is installed
20 on the crane column to operate crane boom relative to axis passing through hinge joints via at least one wire sheave 7 and at least one lifting wire 8 connected to the boom structure. The winch has a heave compensating system (not shown). Relative movement of the pipelines on the platform and on the boom is compensated by chiksan swivels 9. The swivels 9a rotate about the same axis as the crane pedestal and compensate relative movement of the system in horizontal plane. The swivels
25 9b rotate in the same axis as the hinge joints 4 and compensate relative movement of the system in vertical plane. Temperature expansion is taken care of by pipe compensators 10.

In one embodiment of the invention as shown in fig. 3-4, one end of the straight
30 pipes on the boom 5 is connected to inverted V- shaped rigid pipelines with swivel joints 13a that compensate relative longitudinal motion between the platform and the vessel. The other end of the inverted V- shaped rigid pipelines with swivel joints is connected to the other end of straight pipes on the boom hanging on a pipe trolley 14. A connector trolley 15 provides fastening of the boom to a receiving terminal 17
35 and connecting LNG and vapour lines on the boom and on the vessel via chiksan swivels 16. The chiksan swivels prevent forces and bending moments being transferred to the pipes. The connector trolley reciprocates back and forth along the boom structure due to relative longitudinal movement between the platform and the

vessel. All relative roll angles between the platform and the vessel (torsional loads) are taken by the flexible construction of the boom.

5 The connector trolley during offloading operation is attached to the receiving terminal by hinge joints 18 with cone 19 which together can be considered as a universal joint. The hinge joints provide rotating of the boom in vertical plane and compensate pitch angles between the platform and the vessel. The centre of rotation of the hinge joints is in the same axis as centre of rotation of the chiksan swivels 20. The cone 19 with landing skirt 24 is landed on the rotating table 21. The rotating table has series of roller bearings 22 to provide rotation in horizontal plane without transferring loads or/ and moments to the table structure. The rotating table turns in horizontal plane relative to axis passing through centre of the rotating table when relative heading between the platform and the vessel is changed. For connecting and disconnecting of the offloading arm to/ from the receiving terminal, pulling wire 23 and pulling winch installed on the vessel's deck (not shown) with self-tensioning device may be used. The pulling wire and the pulling winch may stay in tension during entire offloading operation.

20 In another embodiment of the invention as shown in fig. 5 – 7, relatively rigid spiral pipes 13b hanging from trolleys 14 on the boom structure compensate relative distance and relative heeling angle between the platform and the vessel. The spiral pipelines are so rigid that it is capable of sustaining a spiral structure under the combined weight of the pipeline and fluid within the pipeline when being suspended on or from the arm 5. The length of the spiral pipes shall be sufficient to compensate relative longitudinal motion between the platform and the vessel, and the rest of the pipe length on the boom could be straight pipe to reduce the weight. 25 The pipe trolleys provide reciprocating movement of the spiral pipes along the boom structures. Connector trolley 15 provides fastening of the boom to the receiving terminal 17 and connecting LNG and vapour lines on the boom and on the vessel via chiksan swivels 16. The chiksan swivels prevent forces and bending moments being transferred to the pipes. The connector trolley reciprocates back and forth along the boom structure due to relative longitudinal movement between the platform and the vessel. All relative roll angles between the platform and the vessel (torsional loads) are taken by the flexible construction of the boom.

35 The connector trolley during offloading operation is attached to the receiving terminal by hinge joints 18 with pin 19 which together can be considered as a universal joint. The hinge joints provide rotating of the boom in vertical plane and compensate pitch angles between the platform and the vessel. The centre of rotation of the hinge joints is in the same axis as centre of rotation of the chiksan swivels 20. The pin 19 with landing skirt 24 is landed on the rotating table 21. The rotating table has series of roller bearings 22 to provide rotation in horizontal plane without transferring loads or/ and moments to the table structure. The rotating table turns in 40

horizontal plane relative to axis passing through centre of the rotating table when relative heading between the platform and the vessel is changed. For connecting and disconnecting of the offloading arm to/ from the receiving terminal, pulling wire 23 and pulling winch installed on the vessel's deck (not shown) with self-tensioning device may be used. The pulling wire and the pulling winch may stay in tension during entire offloading operation.

The invention has now been explained in relation to two embodiments, but various elements may be changes and altered within the scope of the invention as defined in the following claims.
